Start Guide

How to run the Sokoban solver.

1. What you need

- **Python 3.9 or newer.** Check with `python --version`.
- **Tkinter**, which ships with Python on Windows and macOS. On Debian or Ubuntu: `sudo apt install python3-tk`.
- **Nothing else.** No pip install, no virtual environment, no internet connection.

2. Run it

```
cd sokoban-solver
python main.py
```

The window opens on the first level, with the whole pack loaded in the dropdown.

3. Solve a level

- Choose a level from the **Level** dropdown.
- Press **Solve**, or just hit **Enter**.
- The status line counts positions examined while it searches, then reports the push count, move count and time.
- The solution replays on the board automatically. Boxes turn **green** as they land on targets.

4. The controls

Control	Key	What it does
Level dropdown	--	Switches level and resets the board
Solve	Enter	Searches from the CURRENT position; press again to stop
Play / Pause	Space	Pauses and resumes the replay
Reset	R	Puts the level back to its starting position
Move worker	Arrows or WASD	Walk, pushing a box if one is in the way

You can push boxes yourself and then press Enter -- Solve searches from wherever you have got to.

If it will not start

ModuleNotFoundError: tkinter is the only thing that normally blocks a first run. On Linux install `python3-tk`; on Windows, reinstall Python with the *tcl/tk and IDLE* option ticked.
